Mathematics, physics, computers, and the globalisation of culture

Abstract

It is widely believed that globalisation relates to values, and does not concern mathematics, science, and technology, which are value-free, and universal. I will argue to the contrary that mathematics, science and technology are permeated with culture, hence their perceived universality and value-neutrality plays a key role in facilitating the globalisation of culture.

Consider mathematics (on which depend physics and the present-day technology of computing). On the one hand, mathematics is believed to be universal enough to be understood even by extraterrestrials. On the other hand, the history of mathematics informs (or disinforms) us that real mathematics developed only in Greece,[1] and subsequently in Europe after the "renaissance". Setting aside questions about history, isn't it strange that something so allegedly universal could be produced only by a single culture?

In fact, present-day beliefs about mathematics disintegrate if the underlying cultural assumptions are challenged—for example if Buddhist or Jaina logic is used instead of "Aristotelian" logic.[2] I will also briefly indicate what alternative mathematics,[3] science,[4] and technology have been and are being built, free from local religious or theological bias.

The mistaken beliefs in the universality of current mathematics and science affect values. As an example, I analyse the assumptions underlying the perceptions of "reasonable behaviour", as defined in rational choice theory or utilitarianism,[5] and how these perceptions change with beliefs about the nature of time, logic, and computability.

Notes

[1]E.g., Rouse Ball begins his "classic" account of the history of mathematics by triumphantly proclaiming: "The history of mathematics cannot with certainty be traced back to any school or period before that of the Ionian Greeks...".
